

Claims

1. Device in a cable tie comprising an elongate band part (2) of a certain width and thickness, which at one end has an elongate insertion part (3) narrower than the band part (2) and terminating in a grip tab (4), and at its other end has a locking head (1) with, on the one hand, a through-opening (6) which is intended for the band part (2) and is somewhat wider than the band part (2) and has a height somewhat greater than the thickness of the band part (2), and on the other hand a slot-shaped recess (7) in one transverse wall of the opening (6), the width of which recess is such that it will allow the insertion part (3) to be inserted into the opening (6) via the recess (7), forming a band loop, there being tothing (10) on the band part (2) and a locking tongue (8) provided with tothing (9) in the locking head (1), which are designed, by means of a positive interlock, to lock the band part (2) in relation to the locking head (1), characterised in that in the area around the connection of the insertion part (3) to the grip tab (4) there are wing-like projections (11) extending transversely and out from the insertion part (3), which are thinner than the grip tab (4) and which towards the latter terminate in a ridge (12), which ridge in forming the band loop is designed, with the projections (11) inserted into the through-opening (6) of the locking head (1) and bearing against the opposing walls of the opening (6), to abut the locking head (1), the fact that the projections (11) are thinner than the grip tab (4) creating a clearance interval (13) between the insertion part (3) and the locking tongue (8).
2. Device according to Claim 1, characterised in that the projections 11 are incorporated into the grip tab (4).
